

Number Systems (in Binary)

pick up
handout

Today's lecture

- **Representing things with bits**
 - N bits gets you 2^N representations
- **Unsigned binary number representation**
 - Converting between binary and decimal
 - Hexadecimal notation
- **Binary Addition & Bitwise Logical Operations**
 - Every operation has a width
- **Two's complement signed binary representation**

Representing things as bits

- We said everything in computers is bits (e.g., 1's and 0's)
- We do this by associating a pattern of bits with a thing

(like a secret decoder ring...)

Bit pattern	Marine Mammal
0100101	Humpback Whale
0100110	Leopard Seal
0100111	Sea Otter
0101000	West Indian Manatee
0101001	Bottlenose Dolphin

- This mapping however is rarely stored explicitly
 - Rather it is used when we interpret the bits.

How many bits to encode N possible things?

- 1 bit can encode 2 possibilities (0, 1)

$N \text{ bits} \rightarrow 2^N \text{ things}$

Bits = 1	2	3	4
# encodings = 2	4	8	16

What is the minimum # of bits to encode?

- One of the U.S.'s 50 states?

a) 3

b) 4

c) 5

d) 6

e) 7

$\rightarrow 2^5 = 32$

$\rightarrow 2^6 = 64$

How many bits to encode?

- The list of Justin Bieber's good songs?

a) 0

b) 0

c) 0

d) 0

e) 0

Representing Unsigned numbers

- **Unsigned numbers are the set of non-negative numbers:**
 - 0, 1, 2, 3, 4, 5, ...
- **We can only represent a range of these numbers**
 - Based on the # of bits we're using to store the range
 - 3 bits → 0 – 7 (*8 representations*)
 - 8 bits → 0 – 255 (*256 representations*)
- **But what encoding should we use?**

Decimal review

Consider 162.375

- Numbers consist of a bunch of digits, each with a **weight**:

1	6	2	.	3	7	5	Digits
100	10	1		1/10	1/100	1/1000	Weights

- The weights are all powers of the base, which is 10. We can rewrite the weights like this:

1	6	2	.	3	7	5	Digits
10^2	10^1	10^0		10^{-1}	10^{-2}	10^{-3}	Weights

- To find the decimal value of a number, multiply each digit by its weight and sum the products.

$$(1 \times 10^2) + (6 \times 10^1) + (2 \times 10^0) + (3 \times 10^{-1}) + (7 \times 10^{-2}) + (5 \times 10^{-3}) = 162.375$$

Unsigned Binary Number Representation

- We use the same scheme to represent binary numbers, except the weights are powers of **2**.
- For example, here is 1101 in binary:

$$\begin{array}{cccc} \underline{1} & \underline{1} & \underline{0} & \underline{1} & \text{Binary digits, or bits} \\ \underline{2^3} & \underline{2^2} & \underline{2^1} & \underline{2^0} & \text{Weights (in base 10)} \end{array}$$

- The decimal value is:

$$\begin{array}{ccccccc} (1 \times 2^3) & + & (1 \times 2^2) & + & (0 \times 2^1) & + & (1 \times 2^0) = \\ 8 & + & 4 & + & 0 & + & 1 = 13 \end{array}$$

Powers of 2:

$2^0 = 1$	$2^4 = 16$	$2^8 = 256$
$2^1 = 2$	$2^5 = 32$	$2^9 = 512$
$2^2 = 4$	$2^6 = 64$	$2^{10} = 1024$
$2^3 = 8$	$2^7 = 128$	

Binary to Decimal

- What is the 5-bit unsigned number 01010 in decimal?

16 8 4 2 1
 \ / / / /
 1 1
 8 + 2 = 10

a) 2

b) 5

c) 10

d) 12

e) 18

Powers of 2:

$2^0 = 1$	$2^4 = 16$	$2^8 = 256$
$2^1 = 2$	$2^5 = 32$	$2^9 = 512$
$2^2 = 4$	$2^6 = 64$	$2^{10} = 1024$
$2^3 = 8$	$2^7 = 128$	

Decimal Binary

- The same works with decimal binary, but this is uncommon outside of floating point representations.
- For example, here is **1101.01** in binary:

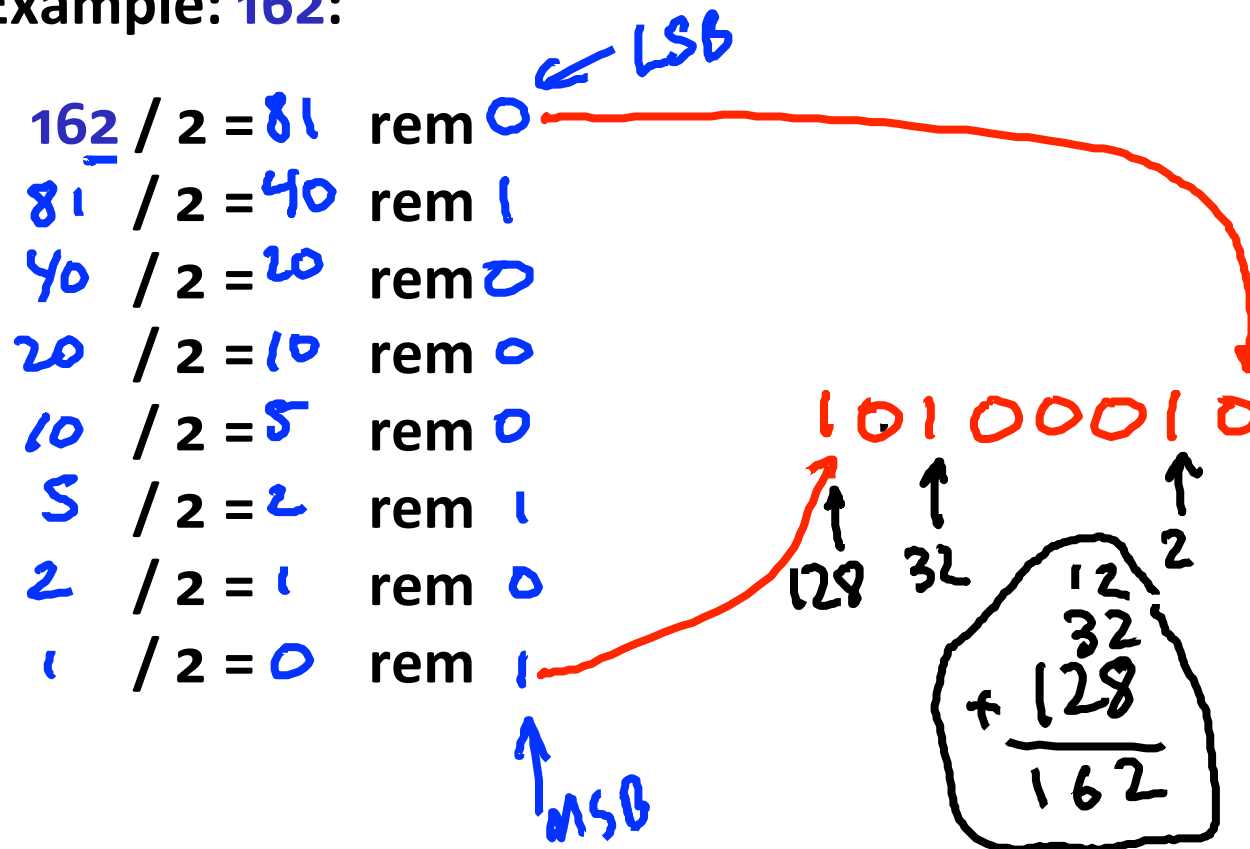

1	1	0	1	.	0	1	Binary digits, or bits
2^3	2^2	2^1	2^0		2^{-1}	2^{-2}	Weights (in base 10)

- The decimal value is:

$$\begin{array}{ccccccccccc} (1 \times 2^3) & + & (1 \times 2^2) & + & (0 \times 2^1) & + & (1 \times 2^0) & + & (0 \times 2^{-1}) & + & (1 \times 2^{-2}) & = \\ 8 & + & 4 & + & 0 & + & 1 & + & 0 & + & 0.25 & = 13.25 \end{array}$$

Converting decimal to binary

- Decimal integer → binary: Keep dividing by 2 until the quotient is 0. Collect the remainders in *reverse* order.
- Example: 162:

Converting decimal to binary

- Decimal integer → binary: Keep dividing by 2 until the quotient is 0. Collect the remainders in *reverse* order.
- Example: 162.375:

$$\begin{array}{lcl} 162 / 2 = 81 & \text{rem } 0 \\ 81 / 2 = 40 & \text{rem } 1 \\ 40 / 2 = 20 & \text{rem } 0 \\ 20 / 2 = 10 & \text{rem } 0 \\ 10 / 2 = 5 & \text{rem } 0 \\ 5 / 2 = 2 & \text{rem } 1 \\ 2 / 2 = 1 & \text{rem } 0 \\ 1 / 2 = 0 & \text{rem } 1 \end{array}$$

To convert a fraction, keep multiplying the fractional part by 2 until it becomes 0. Collect the integer parts in forward order.

$$0.375 \times 2 = 0.750$$

$$0.750 \times 2 = 1.500$$

$$0.500 \times 2 = 1.000$$

- So, $162.375_{10} = 10100010.011_2$

Why does this work?

- This works for converting from decimal to *any* base
- Why? Think about converting 162.375 from decimal to decimal.

$$162 / 10 = 16 \text{ rem } 2$$

$$16 / 10 = 1 \text{ rem } 6$$

$$1 / 10 = 0 \text{ rem } 1$$

- Each division strips off the rightmost digit (the remainder). The quotient represents the remaining digits in the number.
- Similarly, to convert fractions, each multiplication strips off the leftmost digit (the integer part). The fraction represents the remaining digits.

$$0.375 \times 10 = 3.750$$

$$0.750 \times 10 = 7.500$$

$$0.500 \times 10 = 5.000$$

Writing Binary Numbers

- It gets tedious to write 32-bit numbers like:

1001101011100110101100011111101

$$2^4 = 16$$

- It is even more error prone to copy them.

Hexadecimal (base-16)

0x22

22

- The **hexadecimal** system uses 16 digits:

0 1 2 3 4 5 6 7 8 9 A B C D E F
10 6

- We can write our 32bit number:

1001 1010 1110 0110 1011 0001 1111 1101

as

0x9AE6B1FD (C/Java style)

32'h9AE6B1FD (Verilog style)

- Hex is frequently used to specify things like 32-bit IP addresses and 24-bit colors.

Decimal	Binary	Hex
0	0000	0
1	0001	1
2	0010	2
3	0011	3
4	0100	4
5	0101	5
6	0110	6
7	0111	7
8	1000	8
9	1001	9
10	1010	A
11	1011	B
12	1100	C
13	1101	D
14	1110	E
15	1111	F

Hexadecimal to Binary

■ What is $B8_{16}$ in binary?

- A: 10111000
- B: 10100100
- C: 10110100
- D: 11001000

Binary and hexadecimal conversions

- Converting from hexadecimal to binary is easy: just replace each hex digit with its equivalent 4-bit binary sequence.

$$\begin{aligned} 261.35_{16} &= \text{2} \quad \text{6} \quad \text{1} \quad . \quad \text{3} \quad \text{5}_{16} \\ &= \text{0010} \quad \text{0110} \quad \text{0001} \quad . \quad \text{0011} \quad \text{0101}_2 \end{aligned}$$

- To convert from binary to hex, make groups of 4 bits, starting from the binary point. Add 0s to the ends of the number if needed. Then, just convert each bit group to its corresponding hex digit.

$$\begin{aligned} 10110100.001011_2 &= \text{1011} \quad \text{0100} \quad . \quad \text{0010} \quad \text{1100}_2 \\ &= \text{B} \quad \text{4} \quad . \quad \text{2} \quad \text{C}_{16} \end{aligned}$$

Hex	Binary
0	0000
1	0001
2	0010
3	0011

Hex	Binary
4	0100
5	0101
6	0110
7	0111

Hex	Binary
8	1000
9	1001
A	1010
B	1011

Hex	Binary
C	1100
D	1101
E	1110
F	1111

- You can add two binary numbers one column at a time starting from the right, just as you add two decimal numbers.
- But remember that it's binary. For example, $1 + 1 = 10$ and you have to carry!

	0	1	0	1	1	Augend	(11)
+	0	1	1	1	0	Addend	(14)
<hr/>							
	0	1	0	0	1	Sum	(25)

Carry propagation is indicated by blue arrows and numbers below the sum row:

- Arrow 1: From the first column (0) to the second column (1), labeled "16".
- Arrow 2: From the second column (1) to the third column (0), labeled "8".
- Arrow 3: From the fifth column (1) to the sixth column (0), labeled "1".

Binary addition by hand

- You can add two binary numbers one column at a time starting from the right, just as you add two decimal numbers.
- But remember that it's binary. For example, $1 + 1 = 10$ and you have to carry!

The initial carry in is implicitly 0

	1	1	1	0		
	0	1	0	1	1	Carry in
+	0	1	1	1	0	Augend
	0	1	1	1	0	Addend
	1	1	0	0	1	Sum

most significant bit, or **MSB**

least significant bit, or **LSB**

The diagram illustrates the process of binary addition. It shows two numbers, 01011 (Augend) and 01110 (Addend), being added together. The result (Sum) is 11001. The initial carry-in is 0, which is implicitly understood. The carry propagates from the least significant bit (LSB) on the right to the most significant bit (MSB) on the left. The final sum is 11001, where the leading 1 is the carry-out from the MSB column.

Limited representation (4-bit numbers)

- What if we do that same addition, using only 4-bit numbers
 - (and where the result can only be 4 bits long...)

Overflow

we'll talk more later

	1	1	1	1	Augend	(11)
	1	0	1	1		
+	1	1	1	0	Addend	(14)
<hr/>						
X	1	0	0	1	Sum	(9)
	↑			↑		
	1			1		

Bitwise Logical operations

- Most computers also support logical operations like AND, OR and NOT, but extended to multi-bit **words** instead of just single bits.
- To apply a logical operation to two words X and Y, apply the operation on each pair of bits X_i and Y_i :

$$\begin{array}{r} \text{AND } \begin{array}{cccc} 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{array} \\ \hline \begin{array}{cccc} 1 & 0 & 1 & 0 \end{array} \end{array}$$

$$\begin{array}{r} \text{OR } \begin{array}{cccc} 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{array} \\ \hline \begin{array}{cccc} 1 & 1 & 1 & 1 \end{array} \end{array}$$

$$\begin{array}{r} \text{XOR } \begin{array}{cccc} 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{array} \\ \hline \begin{array}{cccc} 0 & 1 & 0 & 1 \end{array} \end{array}$$

Bitwise operations in programming

- Languages like C, C++ and Java provide bitwise logical operations:

& (AND) | (OR) ^ (XOR) ~ (NOT)

- These operations treat each integer as a bunch of individual bits:

$13 \& 25 = 9$ because $01101 \& 11001 = 01001$

- Bitwise operators are often used in programs to set a bunch of Boolean options, or flags, with one argument.

- They are *not* the same as the operators **&&**, **||** and **!**, which treat each integer as a single logical value (0 is false, everything else is true):

$13 \&\& 25 = 1$ because $\text{true} \&\& \text{true} = \text{true}$

Bit-wise XOR

- **001011 XOR 110011**

- A: 111001

- B: 111011

- C: 111000

- D: 000110

Bitwise operations in networking

- IP addresses are actually 32-bit (or 128-bit) binary numbers, and bitwise operations can be used to find network information.
- For example, you can bitwise-AND an address 192.168.10.43 with a “subnet mask” to find the “network address,” or which network the machine is connected to.

$$\begin{array}{rcl} 192.168.10.43 & = & 11000000.10101000.00001010.00101011 \\ \& \ 255.255.255.224 & = & 11111111.11111111.11111111.11100000 \\ \hline 192.168.10.32 & = & 11000000.10101000.00001010.00100000 \end{array}$$

- You can use bitwise-OR to generate a “broadcast address,” for sending data to all machines on the local network.

$$\begin{array}{rcl} 192.168.10.43 & = & 11000000.10101000.00001010.00101011 \\ | \ 0.0.0.31 & = & 00000000.00000000.00000000.00011111 \\ \hline 192.168.10.63 & = & 11000000.10101000.00001010.00111111 \end{array}$$

Negative Numbers

- It is useful to be able to represent negative numbers.
- What would be **ideal** is:
 - If we could use the **same algorithm to add signed numbers as we use for unsigned numbers**
 - Then our computers wouldn't need 2 kinds of adders, just 1.
- This is achieved using the **2's complement representation**.

The number wheel (4-bit unsigned #'s)

The number wheel (4-bit 2's complement)

NEGATIVE
MSB = 1

POSITIVE
MSB = 0
